is an all-in-one tool designed to manage and debug Modbus communications across multiple devices and protocols. It supports various Modbus protocols, including RTU, ASCII, and TCP/IP, allowing you to create multiple connections at once and monitor data from various slave devices. The tool is particularly useful for testing function codes and ensuring your Modbus systems are set up correctly without needing to edit raw data frames manually.

A key feature of the **Redisant Modbus Master Emulator** is its ability to visualize real-time data trends by drawing charts from any number of registers. This helps you see how data changes over time and troubleshoot issues with ease. You can zoom in and out of data points, export charts, and monitor communication traffic on both serial and Ethernet lines. Additionally, it includes stress testing capabilities to simulate heavy loads and assess how well your system can handle increased activity.

Designed to simplify Modbus management, Redisant also includes handy tools for converting data formats like Long, Float, and Double into the correct register formats. The interface is powered by GPU rendering for smooth performance, and the emulator supports up to 28 different data formats. With features like address translation, register grouping, and export/import options for Excel, it offers everything you need to manage Modbus communication networks efficiently.
